

: - Print a window around a line.

Syntax:

```
:  
:n
```

Examples:

```
:  
:3  
/this/:
```

Where:

`n` is a number telling how big the window should be. The default value of `n` is 5. This means the window begins five lines before the specified address and ends five lines after. If you specify a number after the `:`, FRED will use that number for all subsequent `:` commands until you specify a new number.

Description:

`:` displays a window of lines around a single line. If you do not specify an address, FRED displays a window around the current line `". "`. For example, `:` with no arguments before or after is equivalent to `.-5, .+5p`.

`:` sets `". "` to the last line printed.
