

# P - Print.

## Syntax:

P  
<nl>

## Examples:

|   |    |    |         |
|---|----|----|---------|
| p | 5p | *p | ./abc/p |
| 5 | ^  | *  | 1,7     |

## Description:

P displays one or more lines on the terminal. If you do not specify an address, P displays the current line. If you specify one address, P displays that line instead. If you specify two addresses, P displays all the lines between and including the two given lines. In this case, the first address must precede the second. After the lines are printed, P sets "." to the last line printed.

A completely empty line (just the new-line nl character) is equivalent to .P if the current line has changed since the last time it was printed out, and .+1P otherwise. "." is set to whatever line is printed out.

The form

/string/

has one special characteristic: if 0-S/ is in effect, the closing / may be omitted. The same is true with -/string/.
