

ZV - undo V command.

Syntax:

ZV

Examples:

```
s/a/b/
v      "voids the substitution
zv     "undoes the V, so substitution is back
v      "voids the ZV, so sub is undone again
```

Description:

zv undoes the effects of the most recent v command. zv will issue an error if there have been any active commands issued since the last v. (["expl fred v"](#) explains the difference between active and passive commands.) v can be used to undo the effects of zv.

zv does **not** affect the current pattern //. Thus the current pattern will always be the one most recently used in a FRED command, even if the effects of that command have been undone with v or zv.
